2.0 INTRODUCTION

2.1 Purpose and Scope

This document is the Data User Guide for the Level 3 data product for the ECOSystem Spaceborne Thermal Radiometer Experiment on Space Station (ECOSTRESS) project. The Level 3 (L3) PT-JPL product provides evapotranspiration (ET) produced according to the PT-JPL algorithm described in the L3 Algorithm Theoretical Basis Document (ATBD) (JPL D-94645). This document applies to the Level 3 PT-JPL product based upon data acquired by the ECOSTRESS radiometer instrument and will continued to be updated as needed. The purpose of this Data User Guide is to describe the ECOSTRESS end-user L3 data products and provide a guide for their use and interpretation.

2.2 Mission Overview

The ECOSTRESS instrument measures the temperature of plants and uses that information to better understand how much water plants use and how they respond to stress.

ECOSTRESS addresses three overarching science questions:

- How is the terrestrial biosphere responding to changes in water availability?
- How do changes in diurnal vegetation water stress impact the global carbon cycle?
- Can agricultural vulnerability be reduced through advanced monitoring of agricultural water consumptive use and improved drought estimation?

The ECOSTRESS mission answers these questions by accurately measuring the temperature of plants. Plants regulate their temperature by releasing water through pores on their leaves called stomata. If they have sufficient water, they can maintain their temperature. However, if there is insufficient water, their temperatures rise. This temperature rise can be measured with a sensor in space. ECOSTRESS uses a multispectral thermal infrared (TIR) radiometer to measure the surface temperature, deployed on the International Space Station. The instrument measures radiances at 5 spectral bands in the 8-12.5 μm range with approximately 70 by 70 meter of spatial resolution on the ground.

On September 29th 2018, ECOSTRESS experienced an anomaly with its primary mass storage unit (MSU). ECOSTRESS has a primary and secondary MSU (A and B). On December 5th, the instrument was switched to the secondary MSU and operations resumed with initial acquisitions over Australia and wider coverage resumed on January 9th 2019. The initial anomaly was attributed to exposure to high radiation regions, primarily over the Southern Atlantic Anomaly, and the acquisition strategy was revised to exclude these regions from future acquisitions. On March 14th 2019, the secondary MSU experienced an anomaly, and acquisitions are temporarily on hold. Work is underway to implement a direct streaming option, which will bypass the need for mass storage units. The streaming acquisition mode will change the format of the data being collected. Specifically, the new collection mode will eliminate the 1.6 μm (SWIR), 8.2 μm (TIR), and 9.0 μm (TIR) bands. To simplify product formats, the L1 and L2 products will continue to contain the datasets for these bands, but the datasets will contain fill values. This will be seen in products generated after May 15th 2019, when the instrument resumes operations. These changes are described in the detailed product specifications.
2.3 Applicable and Reference Documents

“Applicable” documents levy requirements on the areas addressed in this document. “Reference” documents are identified in the text of this document only to provide additional information to readers. Unless stated otherwise, the document revision level is Initial Release. Document dates are not listed, as they are redundant with the revision level.

2.3.1 Applicable Documents

- ECOSTRESS Project Level 3 Science Data System Requirements (JPL D-94088).
- ECOSTRESS Science Data Management Plan (JPL D-94607)
- 423-ICD-005 ICD Between ECOSTRESS SDS and LPDAAC
- ECOSTRESS Level 1 Algorithm Theoretical Basis Documents (JPL D-94641, D-94642)

2.3.2 Reference Documents

2.4 ECOSTRESS Data Products

The ECOSTRESS mission will generate 13 different distributable data products (Reference Table below). The products represent four levels of data processing, with data granules defined as an image scene. Each image scene consists of 44 scans of the instrument mirror, each scan taking approximately 1.181 seconds, and each image scene taking approximately 52 seconds. Each image scene starts at the beginning of the first target area encountered during each orbit. Each orbit is defined as the equatorial crossing of an ascending International Space Stations (ISS) orbit.

ECOSTRESS Level 0 data include spacecraft packets that have been pre-processed by the Ground Data System (GDS). Level 1 products include spacecraft engineering data, the time-tagged raw sensor pixels appended with their radiometric calibration coefficients, the black body pixels used to generate the calibration coefficients, geolocated and radiometrically calibrated at-sensor radiances of each image pixel, the geolocation tags of each pixel, and the corrected spacecraft attitude data. Level 2 products include the land surface temperature and emissivities of each spectral band retrieved from the at-sensor radiance data, and a cloud mask. Level 2 products also appear in image scene granules. Level 3 products contain evapotranspiration data derived from Level 2 data. Level 4 products contain evaporative stress index and water use efficiency derived from Level 3 data.
The ECOSTRESS products are listed in Table 1-1. This document will discuss only the Level 3 ET_PT-JPL product.

3.0 ALGORITHM AND DATA DESCRIPTION

3.1 The Level 3 role in the ECOSTRESS data system

The ECOSTRESS Level 3 process requires the Level 2 data products for surface temperature and emissivity as well as the Level 1 geolocation information, and a significant number of ancillary data products from other sources (see section 2.2.3). The L3 ET product itself is used for creating the L4 products, Evaporative Stress Index (ESI) and Water Use Efficiency (WUE).

3.2 Input data sets

3.2.1 Requirements on inputs

All input data for the L3 product must be geolocated and time-ordered, and therefore have latitude, longitude, and time associated with each pixel. We do not pose strict requirements on the input products regarding format, projection, and spatio-temporal range. Given the wide range of sources of input data (presented in section x), the fetch and reprojection pipeline described in section x is designed to take care of processing this input data into formats, projections, and subsets as required by the application code described in section x.

3.2.2 ECOSTRESS input products

ECOSTRESS input data products used for the L3 data product are:
● Level 1B – Geolocation
● Level 2 – Land surface temperature
● Level 2 – Surface emissivity
● Level 2 – Cloud Mask

3.2.3 Ancillary input products

Other ancillary input data products used for the L3 data product are:

● MODIS Land
● MODIS Atmosphere
● Landsat 8
● NCEP

See the table below for more detailed information.

</tbody>
</table>

All values in the L3 product are instantaneous at the time of ECOSTRESS overpass, except for daily daytime average latent heat flux (ETdaily). Instantaneous evapotranspiration (ETinst) represents instantaneous latent heat flux in watts per square meter. Uncertainty (ETinstUncertainty) represents the standard deviation of output across three models: PT-JPL, Penman Monteith, and SEBS. The PT-JPL partitions for canopy transpiration (ETcanopy), soil evaporation (ETsoil), and interception evaporation (ETinterception), are given as percentages (from zero to 100) of total latent heat flux.

4.0 SOFTWARE DESIGN

4.1 Overview

The ECOSTRESS pipeline prepares source data from a multitude of remote sensing and reanalysis data products. These source data are retrieved, preprocessed, and resampled to an ECOSTRESS scene. These preprocessed data are run through a series of models to produce the ECOSTRESS product.

4.2 Description of major code sections

4.2.1 Pre-processing pipeline

The downloader PGE begins by calculating which source data granules spatio-temporally intersect the given ECOSTRESS scene. A polygon surrounding the convex hull of latitude/longitude pairs contained in the L1B geolocation arrays is taken as the destination
region. Source regions from Landsat 8 in terms of Landsat path/row are determined by intersecting the target ECOSTRESS polygon with the static set of polygons in the WRS2-Descending region extent system. A static set of polygons in the MODIS Sinusoidal Grid are also intersected against the target footprint of the ECOSTRESS scene to select the horizontal and vertical index pairs for MODIS land products.

Selection of swath granules for the MODIS atmospheric products requires knowledge of the Terra satellite’s orbit. To calculate the orbit of Terra, the Two-Line Element (TLE) observed by the Air Force at the time of ECOSTRESS overpass is queried from spacetrack.com. This TLE is used to calculate the swath ground track of Terra in a 12-hour radius surrounding the ECOSTRESS overpass time using the pyephem library. The boundary of potentially matching MODIS swath granules is calculated by dividing Terra’s swath ground track into 5-minute increments beginning at UTC midnight and applying a constant cross-track swath width. The polygons surrounding these temporally intersecting MODIS swaths are then intersected against the target ECOSTRESS polygon to determine the set of MODIS swath granules that should be retrieved.

With the required granules of source data known, remote servers are crawled to resolve these granules to URLs of available granules for retrieval. Source Landsat 8 files are addressed on Amazon Web Services as individual GeoTIFF files for each band. Addresses for MODIS land data are queried from the Land Processes Distributed Active Archive Center (LP-DAAC) Inventory API. Addressed for MODIS atmosphere granules are obtained by crawling the CSV listings of the Level-1 and Atmosphere Archive & Distribution System Distributed Active Archive Center (LAADS DAAC) HTTP Interface.

With the addresses of required granules recorded, the downloader PGE makes calls to WGET to retrieve these files from the remote servers, organized into a consistent directory structure on the local filesystem. In order to conserve on storage requirements, all runs of the ECOSTRESS downloader retrieve to a collective local mirror. WGET is able to efficiently retrieve only files that it has not already retrieved.

The preprocessor PGE loads and preprocesses the retrieved source data granules. Both Landsat and MODIS record their datasets in 16-bit integer analogs to floating point values. These Digital Numbers (DNs) in the Landsat bands are converted to reflectance using linear parameters read from the Landsat metadata, and these reflectance values are used to calculate NDVI and albedo. Atmospheric and land inputs are ready-made as products in MODIS but are also linearly converted into real units and filtered by accompanying quality flags.

With source data preprocessed at their original locations, these data are ready to be projected onto the target ECOSTRESS scene. Since it is only possible to project between gridded surfaces, intermediate gridded surfaces must be created to represent the source MODIS swaths and destination ECOSTRESS swath. The pyresample library is used to resample by nearest neighbor between swaths and their representative grids. The rasterio library is used to warp data between gridded surfaces, smoothed by cubic interpolation. These techniques are combined to mosaic preprocessed source data over the extent of the ECOSTRESS scene and resample this mosaic.
onto the ECOSTRESS geolocation provided by the L1B product. Finally, these data are stored as the inputs for the PT-JPL and disALEXI PGEs.

This data-store of model forcings passed to the model PGEs is organized by variable and date into a directory structure and written in Hierarchical Dataset Format (HDF5) using the h5py library. HDF5 was chosen as an intermediate file format to accommodate geolocated/non-gridded data.

### 4.2.2 Computation of evapotranspiration

The PT-JPL PGE loads the preprocessed forcing data prepared by the preprocessor PGE and runs them through a sequence of surface energy balance models. All variables, including geolocation, are loaded from the forcing data store created by the preprocessor using the HDF5 library. The Forest Light Environmental Simulator (FLiES) calculates incoming shortwave radiation from atmospheric observations. This is accomplished by querying a multidimensional array of precomputed FLiES model output as a lookup table. The Breathing Earth Systems Simulator (BESS) ingests the ECOSTRESS LST as outgoing longwave radiation. This balance is closed to produce net radiation, the total energy available at the surface. The Priestley-Taylor Jet Propulsion Laboratory (PT-JPL) model calculates transpiration, interception, and soil evaporation from net radiation using the Priestley-Taylor formula constrained by observed land surface properties. These partitions and their total are written to the ECOSTRESS product file using the HDF5 library.

### 5.0 OTHER CONSIDERATIONS

#### 5.1 Error handling

Error handling is managed using Python’s exception handling framework. Exception classes were designed for all foreseeable disruptions to data processing, each of which is assigned a unique exit code that is returned to the Process Control System (PCS).

#### 5.2 Dependencies on existing software

The Anaconda distribution of Python 3.5 was chosen as the platform for the downloader/preprocessor subsystem because of its good support for geospatial data processing. The conda environment manager included in Anaconda provides seamless dependency management for the scientific, geospatial, and data management packages required for ECOSTRESS. These package dependencies include: pandas, affine, ephem, fiona, geopandas, h5py, lxml, netCDF4, nose, numpy, pyproj, python-dateutil, rasterio, requests, shapely, six, spacetrack, bs4, usgs, homura, termcolor, geocoder, scipy,
pyresample, future, pygments, xmltodict, scikit-image, jsonmerge, rasterstats, and untangle.

The C++ language was chosen to implement the PT-JPL model code to maximize the efficiency of processing large arrays. The main dependency linked to by the PT-JPL PGE is the Hierarchical Data Format (HDF) library, which is required for writing the ECOSTRESS product to file.

5.3 Assumptions and limitations

This software assumes daytime acquisition. It is designed not to run for granules acquired at night. This software also assumes precise (< 50 m) geolocation. ECOSTRESS granules that could not be precisely geolocated in the L1B GEO product are not processed into the L3 PT-JPL product. These procedures are in place to ensure that only high-quality raster data are produced in the L3 product, but results in about 1/7 of available ECOSTRESS scenes processing into PT-JPL.

This software also assumes clear-sky conditions. The cloud mask produced in the L2 LSTE product is applied to the L3 product. All pixels considered to be cloud or adjacent to clouds are represented as blank pixels by the IEEE 754 NaN value. This may result in L3 PT-JPL scenes in which a large portion or the entirety of the scene is blank.

5.4 Quality assessment and recording

No original quality flags are produced. Instead the quality flags of the source data products are resampled by nearest neighbor onto the geolocation of the ECOSTRESS scene. A quality flag array for each input dataset, when available, is collected into a combined QA product accompanying the PT-JPL product file.
